(A) VISUAL CONTROL ROBOT SYSTEM.

This invention relates to a visual control robot system for arc welding which can conduct easily and efficiently those operations which are associated with a robot controller and a vision sensor system by an operator through a common operation panel. Before the start of welding, a soft key (9a) disposed on the common operation panel (6) for both the robot controller (5) and vision sensor controller (3) is operated so as to set the robot system to a first mode and under this state, the position of a sample welding member is taught to the robot controller. The soft

key is then operated to switch an operation mode to a second mode in order to input parameters for vision teaching of storing a camera image at each point on a reference weld line formed on the sample weld member. The position teaching and the vision teaching can be given via the same operation panel and moreover, the operation common to both can be carried out by the same operation. Correction control is effected during the welding work so that an actual weld line is in agreement with the reference weld line in accordance with the result of comparison

EP 0 377 755 A1

between an actual camera image representing a welding state and a camera image at the time of vision teaching corresponding to the former.

S P E C I F I C A T I O N VISUALLY CONTROLLED ROBOT SYSTEM

Technical Field

The present invention relates to a visually controlled robot system in which a robot control device and a vision sensor system can be individually operated through a common operator panel.

Background Art

There have been known visually controlled robot systems operated in accordance with visual information detected by a vision sensor. As a typical example, in visually controlled robots for arc wedding, slit light is radiated from a laser beam projector of the vision sensor to a member to be welded, and a slit image is detected by a semiconductor camera of the vision sensor. During a welding process, a vision sensor controller of the robot determines the position of an actual weld line by analyzing the slit image and detects a deviation of the actual weld line from a reference weld line formed on a sample weld member for vision teaching, and the robot control device performs a correction in accordance with the detected deviation so that the actual weld line and the reference weld line coincide, while carrying out an arc welding. Here, the vision teaching denotes a process of storing camera pictures obtained with a laser beam sequentially radiated to a plurality of points on the reference weld line formed beforehand on the sample weld member when a welding operation is stopped, in the vision sensor controller in relation to robot operated positions. The slit images in the camera pictures obtained at the individual points on the weld line of the sample weld member exhibit characteristic portions representing the position of the weld line. For example, in the case of

a lap joint, the slit image contains a disconnected portion as a characteristic portion, and in the case of a fillet welded joint, the slit image contains a bent point as a characteristic portion. Thus, the characteristic portions of the slit images in a plurality of camera pictures cooperatively indicate the reference weld line.

5

10

25

30

When carrying out a vision teaching, the operator must input various parameters for the vision teaching to the vision sensor controller. Therefore, conventionally, an operator panel used exclusively for the robot control device to teach actions to the robot and an operator panel used exclusively for the arc vision sensor system are separately provided.

Accordingly, the operator must be skilled in the operation of these two operator panels and must operate the panels alternately, suffering a laborious and inefficient operation.

Disclosure of the Invention

An object of the present invention is to provide a visually controlled robot system which permits an operator to easily and efficiently carry out operations individually related to a robot control device and a vision sensor system through a common operator panel.

To achieve the above object, according to the invention, there is provided a visually controlled robot system comprising a robot control device for controlling an operation of a robot body, a vision sensor system for detecting visual information, and a common operator panel having means for selecting one of a first mode for carrying out an operation related to the robot control device and a second mode for carrying out an operation related to the vision sensor system, to carry out the operations.

According to the present invention, operations individually related to the robot control system and vision sensor system of the visually controlled robot system can be carried out through the common operator panel, and therefore, the operator can easily perform an operation related to the robot control device and an operation related to the vision sensor system by simply switching the operation modes of the robot system, using the only one operator panel, whereby the operating efficiency is improved. Furthermore, the operator can easily get skilled in the manipulation of the operator panel.

Brief Description of the Drawing

10

15

20

25

30

The single figure is a diagram showing, partly in blocks, a visually controlled robot system for arc welding according to an embodiment of the invention.

Best Mode of Carrying Out the Invention

In the figure, a visually controlled robot system for arc welding comprises a robot body 1, and a welding torch 2a and an arc vision sensor 2b, which are mounted to a wrist portion 2 of the robot 1. The vision sensor 2b constitutes an arc vision sensor system in cooperation with an arc vision sensor controller 3 having a CRT display 4, and is provided with a laser beam projector including a laser oscillator, and a semiconductor camera (none of them are shown). The welding torch 2a and the projector and camera of the sensor 2b are always in a predetermined positional relationship relative to one another. The robot body 1 is provided with servomotors (not shown) serving as means for driving individual axes of the robot, and various internal sensors (not shown) for detecting the operated positions of the servomotors for the individual axes. The servomotors and the internal

sensors are connected to a robot control device 5 comprising, e.g., a numerical control device.

The robot system is further provided with an operator panel 6, which is connected to the robot control device 5 and also connected through the control device 5 to the arc vision sensor controller 3 such that various operations individually related to the control device 5 and the vision sensor system can be carried out through the common operator panel 6. Namely, the robot system is operable in various modes 10 including a first mode for carrying out an operation related to the robot control device 5 and a second mode for carrying out an operation related to the arc vision sensor system (more specifically, the arc vision sensor 15 controller 3), and the operator panel 6 is provided with means for selecting one of these modes. Specifically, the operator panel 6 comprises a liquidcrystal display section 7, various keys/buttons 8 including cursor keys and ten-key pad, and a plurality 20 of software keys 9. The software keys 9 have different functions in different modes of the robot system, whereby a large number of functions can be executed. For example, a predetermined software key 9a is designed to function as the aforementioned mode selection means when the robot system is powered. **25** · Moreover, the robot system is constructed such that operations common to both the first and second modes (e.g., an operation for moving the cursor on the screens of the CRT display 4 and the liquid-crystal display section 7, etc.) can be executed by operating 30 the keys/buttons of the operator panel 6 in the same manner.

Now, the operation of the arc welding robot system constructed as above will be described.

5

10

15

20

25

30

In the robot system, teaching of the position of a weld member, teaching of welding conditions, vision teaching, and an actual welding process are executed in the order mentioned.

First, the operator sets a sample weld member on a jig (neither is shown) and turns on the power of the robot system. Upon application of the power, the arc vision sensor controller 3 causes the liquid-crystal display section 7 of the operator panel 6 to display a mode selection screen. In this screen, various functions imparted to the respective software keys 9 at the time of the mode selection are displayed. The operator operates the predetermined software key 9a which then functions as the mode selection means, to select the first mode for carrying out an operation related to the robot control device 5.

Next, by pressing the various keys/buttons 8 of the operator panel 6, the operator manually operates the robot body 1 through the robot control device 5 to teach the position of the sample weld member (specifically, the operated positions of the servomotors for the individual axes detected by the internal sensors) to the robot control device 5. Then, the operator carries out a tentative welding on the sample weld member, and sets the resultant proper welding conditions obtained in the robot control device 5.

Subsequently, to carry out the vision teaching, the operator presses the software key 9a of the operator panel 6 to display the mode selection screen at the liquid-crystal display section 7, and selects the second mode for carrying out an operation related to the arc vision sensor system. In accordance with this mode selection, the arc vision sensor controller 3

- 6 -

sequentially displays messages questioning about the vision teaching, at the liquid-crystal display section 7. The operator presses the keys/buttons 8 of the operator panel 6 in answer to the questions, to thereby set parameters relating to the vision teaching, such as a region for image analysis on the screen of the CRT display 4, a type of a joint, an image acquisition interval, etc.

5

In accordance with the vision teaching parameters 10 thus set, the vision sensor controller 3 cooperates with the robot control device 5 to carry out a vision teaching operation. At the time of the vision teaching, a welding process is stopped. vision teaching is carried out, the robot control device 5 controls the operation of the robot body 1 in 15 accordance with the teaching on the position of the aforesaid sample weld member, such that the welding torch 2a attached to the wrist portion 2 of the robot body 1 is moved along the reference weld line formed on 20 the sample weld member. During this time, slit light with a linear section extending in the direction of traversing the weld line of the sample weld member is radiated from the laser beam projector of the vision sensor 2b toward the sample weld member, and a slit image (a V-shaped bent line, if the sample weld member 25 is a fillet welded joint) is detected by the semiconductor camera of the sensor 2b. The slit image is displayed on the screen of the CRT display 4 associated with the vision sensor controller 3 connected to the semiconductor camera. 30 The vision sensor controller 3 reads camera pictures including the slit images into a storage device incorporated therein at predetermined intervals of time (corresponding to a distance of 2 to 50 mm on the weld line) and in

5

10

15

20

25

30

relation to the position and orientation of the wrist portion 2 of the robot body 1.

As mentioned above, during individual operations in the first and second modes, the operator carries out a necessary operation by using only the operator panel 6 common to these modes, and operations common to these two modes are effected by operating the keys/buttons of the operator panel 6 in the same manner, whereby even an unskilled person can easily and efficiently carry out an operation in these two modes.

After the above-described various operations are finished, the operator sets a weld member which is to be actually welded, and operates the operator panel 6 to put the robot system in a welding operation mode, thereby starting a welding process.

During an arc welding process, the robot control device 5 controls the position and orientation of the wrist portion 2 of the robot body 1 (i.e., the position and orientation of the welding torch 2a) in accordance with the teaching on the position of the aforesaid sample weld member, read from the built-in storage device, and carries out a welding under the proper welding conditions determined in the aforesaid manner. In this welding process, slit light is radiated from the laser beam projector of the vision sensor 2b toward the weld member, as in the vision teaching process, whereby a current welded state is imaged by the camera of the sensor 2b and displayed on the CRT screen. vision sensor controller 3 reads the camera picture when the welding torch 2a reaches each of predetermined points on the weld line, and also reads out a camera picture whose torch position corresponds to that of the currently read picture, from among the camera pictures stored in the built-in storage device at the time of

- 8 -

the vision teaching. Next, the vision sensor controller 3 carries out an image analysis on each of the two camera pictures and extracts characteristic portions of the slit images contained the camera 5 pictures which represent the weld line (e.g., a bent point of the V-shaped bent line if the weld member is a fillet welded joint). Then, the controller 3 calculates the magnitude of the on-screen deviation between the characteristic portions of the two camera 10 pictures, and calculates the actual dimensions (correction amounts) of the deviation between the reference weld line used at the vision teaching and the actual weld line for the welding process, based on the calculated magnitude value and a scale factor determined in accordance with the known distances 15 between the laser beam projector and the camera and between the projector and the welding member. The deviation of position is caused by a setting error of a workpiece, shifting of the position of the workpiece 20 during a welding process, etc. The vision sensor controller 3 then sends the aforesaid correction amounts to the robot control device 5, and in accordance with the correction amounts, the robot control device 5 carries out a real-time correction of 25 the weld path. This correction is effected at each of the points on the weld line, whereby arc welding can be carried out with accuracy.

CLAIMS

- 1. A visually controlled robot system comprising:
- a robot control device for controlling an operation of a robot body;
- 5 a vision sensor system for detecting visual information; and

10

15

20

- a common operator panel having means for selecting one of a first mode for carrying out an operation related to said robot control device and a second mode for carrying out an operation related to said vision sensor system, to carry out said operations.
- 2. A visually controlled robot system according to claim 1, wherein said vision sensor system includes a vision sensor for imaging at least a subject of work, and a vision sensor controller for analyzing a picture signal from said vision sensor, said vision sensor controller being connected to said operator panel.
- 3. A visually controlled robot system according to claim 1, wherein an operation common to said first and second modes is executed through an identical operation of the operator panel by an operator.
- 4. A visually controlled robot system according to any one of claims 1 to 4, wherein a welding torch is mounted to said robot body to carry out arc welding.
